

Laravel Developer

This test has been designed to allow us to see your PHP knowledge and how you approach a problem.

Goals

There are a few key goals to keep in mind with this test:

- Remote APIs are often unstable and unreliable; how will you handle this?
 - Consider how you will communicate API errors to other developers utilising this package.
 - How can you make a generic exception thrown by an API or third party package more specific to your domain?
 - Will you let exceptions propagate or catch and handle them in some form?
- How can you make your code testable?
 - How will you make your own code testable? Demonstrate this by providing unit tests.
 - How will you make your unit tests work when interacting with a remote API? Would your tests still pass if the API was offline or the data on the API changed? If not, how would you avoid this issue?
- Don't feel the need to reinvent the wheel; if there's a well established composer package that could help, feel free to use it, but we still need to see intelligent choices in packages selected and meaningful implementation. This should be limited to standalone packages, not the use of entire frameworks.
- Make it framework agnostic. This package should work in Laravel, Drupal, Wordpress, and any other PHP software just as easily with no reliance on being used in any particular scenario.
- Code should be well typed and written to clean, modern PSR standards targeting PHP 8.4.
- Use of PHPStan static analysis is highly recommended to demonstrate the intent and the correctness of your code.

The Task

Create a framework-agnostic Composer package that provides a service for retrieving and

creating users via a remote API (integrate with the <https://dummyjson.com/docs> dummy API for the purposes of this test).

The service should provide:

- A method to retrieve a single user by ID
- A method to retrieve a paginated list of users
- A method to add a new user, providing a firstname, lastname and email, and returning a User ID.
- All users returned by the service must be converted into well defined DTO models implementing JSON serializable interfaces and supporting conversion to a standard array structure. Only the firstname, lastname, email and ID are needed to be collected.

The package must include unit tests for your service and may include integration and/or API tests.

Please do not submit this task to Packagist or any other composer package distributor.
